I would like to apply an update to multiple documents by this key. The closest solution I've found is to loop through each record\_id, do an update with a \$set operation and then sort by the timestamp field of each document. But this approach would be slow for large amounts of data. So how can I write a query to apply multiple updates? A: MongoDB provides the aggregation framework, which is optimized for large amounts of data. It was designed to work on this kind of problem. The basic approach is to group documents by the field you're interested in (here: record\_id), calculate the value you want to update, and update all documents. The Aggregation Framework basically works like a loop with the \$group operator (actually, the \$group operator is just a convenience that is applied to multiple arrays at once): db.collection.aggregate( [ { "\$group": { "\_id": "\$record\_id", "value": { "\$sum": 1 } } } ] ) This is a short summary, but here is a much more detailed tutorial: Edit: If you want to update the same value for all the records (i.e. you want 2d92ce491b
